

# Tebas Script

Documentation for Tebas Script v0.5.1, by Siljam.

<https://github.com/siljamdev/Tebas>

## Scripts

Scripts are files, usually with the `.tbscr` extension.

These scripts are used in Tebas templates and plugins, and are aimed at providing an easy way to create these templates. They are based around strings and their operations(as you will soon see).

Each file is divided by lines and each line is a **sentence**. The code is interpreted at runtime, line by line.

## Tables and strings

Before explaining normal sentences, we first must understand the central concept of tables. Tables are global variables that do not need to be initialized. They are dynamic arrays of strings that can contain any values.

The syntax used to access tables is the following:

```
table.index  
  
deck.0  
deck.1  
deck.-1  
deck.random  
deck.length
```

Tables are 0 indexed, so the first element is element 0. We can also access things starting from the end instead of the start. Element -1 is the last element, element -2 is the previous and so forth.

You can also access *length*, *random* and *center* properties. *length* is the length of the table, as a string, *random* returns an element chosen at random and *center* returns the element in the middle.

# Arguments

Sentences are divided into command and arguments. The parts are divided by whitespace, but whitespace is allowed inside of quotes or square brackets.

There are 3 types of arguments:

## Strings

These can be thought of as text. They can be values from a table or literals.

```
"Hello World!"  
f"Hello {deck.0}"  
deck.0
```

Literals are written between double quotes "", to escape one of them use the backslash \. Also, \n will be replaced by a newline.

Literals with a preceding *f* will be expanded, explained later.

There are also special values, that are preceded by %.

```
%pn //Project name  
%tn //Template name  
%wd //Working directory  
%td //Template directory  
%pl //Current plugin name  
%d //Current date and time, in the dd/MM/yyyy HH:mm:ss format  
%h //Current time, in the HH:mm:ss format  
%os //Os, its either 'windows', 'linux' or 'macos'  
%tbv //Tebas version  
%tbx //Full path to the tebas executable
```

## String references

This arguments are used mostly in sentences that return values, they symbolized where to put the output value. Note that you cannot use *length* here, as it is read-only.

```
deck.1  
show.0
```

## Tables

The tables themselves, you can either reference a global table or write a literal.

```
[“value 1”, f“value {num.2}”]
```

```
deck  
args
```

Literals are written between square brackets [] and they include string literals separated by commas.

## Table references

This arguments are used mostly in sentences that return values, they symbolized where to put the output value.

```
deck  
show
```

## Special tables

There are some special tables that have some functionality.

### args

This is the command line args that the script was called with. These are usually command line arguments.

### true and false

These two are initialized with 1 and 0 respectively and are used for all Boolean operations or logic handling. You can set them to something custom or add extra values.

### error

When an error occurs, this table will be erased and a single entry will be added, a description of the error. Also, information will appear on the console.

## Flow control sentences

Flow control happens in blocks, encased with curly brackets {}. It is important to leave whitespace before brackets.

Now, a list of all sentences will be provided along with what they do and their format. For the arguments, *s* will be used to symbolize a string argument, *\*s* for a string reference, *t* for a table and *\*t* for a table reference.

## exit

Used to instantly exit the script.

```
exit
```

## function

Used to define a function, with a name. It can be called at any moment. Functions do not have arguments, but all tables are global.

```
function name {  
    body  
}
```

## return

Used inside a function, to return immediately.

```
return
```

## call

Used to invoke functions.

```
call name
```

## scope

This sentence only makes sense inside a function. It is used to have local data that makes no sense outside of the function. Only one table can be declared the local scope per function. The value of that table is saved when entering the function and retrieved when passing control to other functions or finishing, so that table can be also used outside.

```
scope *t
```

## while

Used for while loops, common in many programming languages. The condition is a string, that will be evaluated as a boolean. You can also use *while!*, and the condition will be reversed (false needed).

```
while s {  
    body  
}
```

## do

Used for do-while loops. However, the condition is at the start of the loop, but is evaluated at the end. *do!* Also exists.

```
do s {  
    body  
}
```

## continue

This sentence only makes sense inside a while or do loop. It continues to the next iteration of the loop, skipping the remaining code.

```
continue
```

## break

This sentence only makes sense inside a while or do loop. It breaks out of the loop, skipping the remaining code and iterations.

```
break
```

## if-elseif-else

Sentences used for if(or if!) statements. In the same sentence as the closing bracket of the main if statement, you can include the *elseif* (or *elseif!*) or *else*.

```
if s {  
    body  
} elseif s {  
    body  
} elseif! s {  
    body  
} else {  
    body  
}
```

## Action sentences

Now, a list of all sentences will be provided, grouped together in groups, along with what they do and their format. For the arguments, *s* will be used to symbolize a string argument, *\*s* for a string reference, *t* for a table and *\*t* for a table reference.

### console

```
console.print s
```

Prints a string into the console.

```
console.printExpand s
```

Prints a string into the console. This string will be expanded (string expansion is explained later).

```
console.printFormat s
```

Prints a string into the console with the *FormatString* format applied (From AshLib).

To understand this, this is the format:

```
'/[c#,ff5900]Hello /[rc]World'
```

This will display Hello in orange and World in the original console color

```
console.pause s
```

Will output a string into the console and then wait for any key to be pressed to continue.

```
console.ask *s s
```

Will output a string(2<sup>nd</sup> arg) to the console and then let the user type an answer, which is outputted in the first arg.

## process

```
process.cmd s
```

Starts cmd (or similar in other OS) process with commands as arguments.

```
process.link s
```

Opens a link on the default browser.

```
process.run s s
```

Starts process(1<sup>st</sup> arg) with cli arguments(2<sup>nd</sup> arg).

```
process.runDetached s s
```

Starts process(1<sup>st</sup> arg) with cli arguments(2<sup>nd</sup> arg) on a different window.

```
process.runOutput s s *t *t
```

Starts process(1<sup>st</sup> arg) with cli arguments(2<sup>nd</sup> arg), and outputs the process output into the table in 3<sup>rd</sup> arg and the process errors into the table in 4<sup>th</sup>.

```
process.runExitCode *s s s
```

Set a string to the numerical exit code of the process(1<sup>st</sup> arg) with cli arguments(2<sup>nd</sup> arg).

```
process.isExecutableInPath *s s
```

Sets the string(1<sup>st</sup> arg) to true if the PATH environment variable contains a mention to the executable with name 2<sup>nd</sup> arg, false otherwise.

```
process.getExecutableFullPath *s s
```

Sets the string(1<sup>st</sup> arg) to the full path of a executable that is in the PATH environment variable with name 2<sup>nd</sup> arg.

## time

```
time.wait s
```

Reads the string as a number and waits that number of milliseconds.

## string

```
string.set *s s
```

Sets a string

```
string.expand *s s
```

Sets a string to another string expanded.

```
string.append *s s s
```

Sets a string to two strings concatenated.

```
string.split *t s t
```

Sets the table to the string in 2<sup>nd</sup> arg splitted, using 3<sup>rd</sup> arg as separators.

```
string.splitChars *t s
```

Sets the table to the string in 2<sup>nd</sup> arg splitted into individual characters.

```
string.substring *s s s s
```

Sets a string to another string(2<sup>nd</sup> arg) substring. 3<sup>rd</sup> arg is start index(0 based) and 4<sup>th</sup> is length.

```
string.replace *s s s s
```

Sets a string to another string where the 3<sup>rd</sup> string has been replaced by the 4<sup>th</sup> string in the 2<sup>nd</sup> string.

```
string.equal *s s s
```

Sets a string to true if two strings are equal, or true if they are not.

```
string.lower *s s
```

Sets a string to lowercase of another string

```
string.upper *s s
```

Sets a string to uppercase of another string

```
string.contains *s s s
```

Sets a string to true if a string contains a substring, and false otherwise.

```
string.trim *s s
```

Sets a string to another string where the start and end whitespace has been removed.

```
string.removeQuotes *s s
```

Sets a string to another string has been attempted to remove double quotes “” if it was encased in them.

```
string.count *s s
```

Sets a string to the length of another string.

## self

```
self.expand *s
```

A string is set to itself expanded.

```
self.append *s s
```

A string is set to itself concatenated with another string.

```
self.substring *s s s
```

A string is set to a substring of itself. 2<sup>nd</sup> arg is start index(0 based) and 3<sup>rd</sup> is length.

```
self.replace *s s s
```

A string is set to itself where it got a string(2<sup>nd</sup> arg) replaced by another string(4<sup>th</sup> arg)

```
self.upper *s
```

A string is set to itself in uppercase.

```
self.lower *s
```

A string is set to itself in lowercase.

```
self.trim *s
```

A string is set to itself where the start and end whitespace has been removed.

```
self.removeQuotes *s
```

A string is set to itself where it has been attempted to remove double quotes "" if it was encased in them.

## table

```
table.access *s *t s
```

Sets a string(1<sup>st</sup> arg) to an string from the table(2<sup>nd</sup> arg) using the 3<sup>rd</sup> string as the index. You can still use random and center here.

```
table.setAt *t s s
```

Sets a string from the table in the first arg, using the 2<sup>nd</sup> arg as index, and the 3<sup>rd</sup> arg as the value to set it to.

```
table.delete *s
```

Delete a string from its table. Tables are dynamic, so the next item will occupy its place.

```
table.deleteAt *t s
```

Deleting a string from a table. 2<sup>nd</sup> arg is used as the index. Tables are dynamic, so the next item will occupy its place.

```
table.insert *s s
```

Inserting a value(2<sup>nd</sup> arg) in a string in the table. Tables are dynamic, so the next item will move down.

```
table.insertAt *t s s
```

Inserting a value(3<sup>rd</sup> arg) into a table(1<sup>st</sup> arg), using 2<sup>nd</sup> arg as index.

```
table.contains *s t s
```

Sets a string(1<sup>st</sup> arg) to true if the table(2<sup>nd</sup> arg) contains the string(3<sup>rd</sup> arg), false otherwise.

```
table.clear *t
```

Clears a table to its empty state

```
table.add *t s
```

Adds a string to the end of a table. Useful for using tables as stacks, this is what is commonly called push.

```
table.append *t t
```

Adds multiple strings(a table, 2<sup>nd</sup> arg) to the end of a table.

```
table.pop *s *t
```

Sets a string to the last element of a table and deletes that element. Useful for using tables as stacks.

```
table.peek *s *t
```

Sets a string to the last element of a table without deleting that element. Useful for using tables as stacks.

```
table.set *t t
```

Sets a table.

```
table.shuffle *t t
```

Sets a table to another table(2<sup>nd</sup> arg) randomly shuffled.

```
table.join *s t s
```

Sets a string to a table joined together, using the 3<sup>rd</sup> arg as separator.

## bool

```
bool.isBool *s s
```

Sets a string to true if another string can be interpreted as a bool.

```
bool.negate *s s
```

Sets a string to the negated bool of another(uses true and false tables, described earlier).

```
bool.and *s s s
```

Sets a string to true if both strings are true.

```
bool.or *s s s
```

Sets a string to true if at least one string is true.

## math

```
math.isNumber *s s
```

Sets a string to true if the string can be parsed to a number(int). Numbers are represented as parsable strings.

```
math.isNegative *s s
```

Sets a string to true if the string is a negative number.

```
math.equal *s s s
```

Sets a string to true if the strings represent the same number.

```
math.getRandom *s s s
```

Sets a string to a random number between the 2<sup>nd</sup> arg(inclusive) and the 3<sup>rd</sup>(exclusive).

```
math.sumUp *s s
```

Sets a string to the result of adding 1 to another(2<sup>nd</sup> arg).

```
math.sumDown *s s
```

Sets a string to the result of subtracting 1 to another(2<sup>nd</sup> arg).

```
math.sum *s s s
```

Sets a string to the result of adding two numbers together (2<sup>nd</sup> and 3<sup>rd</sup> args).

```
math.subtract *s s s
```

Sets a string to the result of subtracting the 3<sup>rd</sup> arg from the 2<sup>nd</sup>.

```
math.multiply *s s s
```

Sets a string to the result of multiplying two numbers together (2<sup>nd</sup> and 3<sup>rd</sup> args).

```
math.divide *s s s
```

Sets a string to the result of dividing the 2<sup>nd</sup> arg by the 3<sup>rd</sup>. This is integer division, no floating point.

```
math.modulus *s s s
```

Sets a string to the result of performing modulus operation(equivalent to % operator in c).

```
math.abs *s s
```

Sets a string to the absolute value of the number as arg.

```
math.greater *s s s
```

Sets a string to true if the 2<sup>nd</sup> arg is greater than the 3<sup>rd</sup>, false otherwise.

```
math.greaterEqual *s s s
```

Sets a string to true if the 2<sup>nd</sup> arg is greater or equal than the 3<sup>rd</sup>, false otherwise.

```
math.less *s s s
```

Sets a string to true if the 2<sup>nd</sup> arg is less than the 3<sup>rd</sup>, false otherwise.

```
math.lessEqual *s s s
```

Sets a string to true if the 2<sup>nd</sup> arg is less or equal than the 3<sup>rd</sup>, false otherwise.

## path

```
path.extension *s s
```

Sets a string to the extension (including the dot .) of the file, providing the path in the 2<sup>nd</sup> arg. More on paths later.

```
path.filename *s s
```

Sets a string to the file name and extension of a file providing its path. For example  
*folder/folder/hello.txt => hello.txt*

```
path.filenameNoExtension *s s
```

Sets a string to the file name of a file providing its path. For example  
*folder/folder/hello.txt => hello*

```
path.directory *s s
```

Sets a string to the directory containing a file.

## file

```
file.create s
```

Creates a file if it doesn't exist already, providing its path.

```
file.read *s s
```

Sets a string to the full contents of a file, providing its path(2<sup>nd</sup> arg).

```
file.delete s
```

Deletes a file based on its path

```
file.rename s s
```

Renames a file from old name(1<sup>st</sup> arg) to new name(2<sup>nd</sup> arg).

```
file.copy s s
```

Copies a file from path(1<sup>st</sup> arg) to new path(2<sup>nd</sup> arg).

```
file.write s s
```

Writes content to a file, overriding it. 1<sup>st</sup> arg is the path, and 2<sup>nd</sup> is the content.

```
file.append s s
```

Writes content to a file, adding it to the end. 1<sup>st</sup> arg is the path, and 2<sup>nd</sup> is the content.

```
file.exists *s s
```

Sets a string to true if a file exists, providing its path(2<sup>nd</sup> arg). False otherwise.

```
file.size *s s
```

Sets a string to the size of a file, in bytes, providing its path(2<sup>nd</sup> arg).

```
file.isExecutable *s s
```

Sets a string to true if a file exists and is an executable, provided its path(2<sup>nd</sup> arg). False otherwise.

## folder

```
folder.create s
```

Creates a directory, provided its path. More on paths later.

```
folder.delete s
```

Deletes a directory, provided its path.

```
folder.rename s s
```

Renames a folder, provided the old name(1<sup>st</sup> arg) and its new name(2<sup>nd</sup> arg).

```
folder.exists *s s
```

Sets a string to true if a directory exists, provided its path(2<sup>nd</sup> arg). False otherwise.

```
folder.list *t s s
```

Sets a table to the list of existing files inside a directory, provided its path(2<sup>nd</sup> arg) and a format(3<sup>rd</sup> arg). This format can contain wildcards, for example '\*' or '\*.txt'.

```
folder.listChild *t s s
```

Sets a table to the list of existing files inside a directory and its subdirectories, provided its path(2<sup>nd</sup> arg) and a format(3<sup>rd</sup> arg). This format can contain wildcards, for example '\*' or '\*.txt'.

## template

```
template.read *s s
```

For scripts that work inside a template, gets a saved resource from the template, using the 2<sup>nd</sup> arg as name.

```
template.write s s
```

Writes a resource into the current template. Its value will be overwritten. 1<sup>st</sup> arg is the resource name and 2<sup>nd</sup> is the content.

```
template.append s s
```

Writes a resource into the current template. Its value will be added to the end. 1<sup>st</sup> arg is the resource name and 2<sup>nd</sup> is the content.

```
template.run s s
```

Runs a script from the current template. 1<sup>st</sup> arg is the script name, and 2<sup>nd</sup> arg is cli arguments. These are a continuous string, but will be split like cli args do.

```
template.global s s s
```

Runs a global script from a template. 1<sup>st</sup> arg is the template name, 2<sup>nd</sup> arg is the script name, and 3<sup>rd</sup> arg is cli arguments. These are a continuous string, but will be split like cli args do.

```
template.installed *s s
```

Sets a string to true if a template with 2<sup>nd</sup> arg as name is installed, false otherwise.

```
template.list *t
```

Returns a table with the names of all installed templates.

```
template.create s
```

Create a template using the creator utility. It is the equivalent of doing the cli command. The arg is the path.

## plugin

```
plugin.read *s s s
```

Sets a string(1<sup>st</sup> arg) to the result of reading a resource from a plugin. The 2<sup>nd</sup> arg is the name of the plugin, and the 3<sup>rd</sup> arg is the name of the resource.

```
plugin.write s s s
```

Saves a plugin resource. 1<sup>st</sup> arg is the name of the plugin, 2<sup>nd</sup> arg is the name of the resource, and 3<sup>rd</sup> arg is the content being written.

```
plugin.append s s s
```

Saves a plugin resource, this value will be appended to the end. 1<sup>st</sup> arg is the name of the plugin, 2<sup>nd</sup> arg is the name of the resource, and 3<sup>rd</sup> arg is the content being written.

```
plugin.run s s s
```

Runs a script from a plugin. 1<sup>st</sup> arg is the name of the plugin, 2<sup>nd</sup> arg the name of the script, and 3<sup>rd</sup> arg is cli commands.

```
plugin.installed *s s
```

Sets a string to true if a plugin(name is 2<sup>nd</sup> arg) is installed, false otherwise.

```
plugin.list *t
```

Gets a list of installed pugins.

```
plugin.create s
```

Create a plugin using the creator utility. It is the equivalent of doing the cli command. The arg is the path.

## shared

```
shared.read *s s
```

Reads a value from the shared resources (available to all templates, plugins and scripts) based on its name.

```
shared.write s s
```

Writes a value to the shared resources (available to all templates, plugins and scripts). 1<sup>st</sup> arg is name, 2<sup>nd</sup> arg is content.

```
shared.append s s
```

Appends a value to the end of a resource (available to all templates, plugins and scripts). 1<sup>st</sup> arg is name, 2<sup>nd</sup> arg is content.

## project

```
project.read *s s
```

If there is currently a local project active, it reads a resource from the project file. 2<sup>nd</sup> arg is the resource name.

```
project.write s s
```

It writes a resource to the local project. 1<sup>st</sup> arg is the resource name, and 2<sup>nd</sup> is the content.

```
project.append s s
```

It appends to the end of a resource. 1<sup>st</sup> arg is the resource name, and 2<sup>nd</sup> is the content.

```
project.gitUsed *s
```

Sets a string to true if git is being used in the current project.

```
project.getCurrentGitBranch *s
```

Sets a string to the current git branch\_of the project.

```
project.remoteSet s s
```

Equivalent of doing the cli command, 1<sup>st</sup> arg is the remote name, and 2<sup>nd</sup> arg is the remote url.

```
project.remoteUrl *s s
```

Sets a string to the url of a remote based on its name(2<sup>nd</sup> arg).

```
project.remoteDelete s
```

Equivalent of doing the cli command, 1<sup>st</sup> arg is the remote name.

```
project.remoteList *t
```

Sets a table of all the remote names of the current local project.

```
project.remoteExists *s s
```

Sets a string to true if a remote exists(2<sup>nd</sup> arg as remote name), false otherwise.

## tebas

```
tebas.commit s
```

Equivalent of doing the cli command. Commits to git. The argument is the commit message.

```
tebas.push s
```

Equivalent of doing the cli command. Commits to git. The argument is the remote.

```
tebas.pull s
```

Equivalent of doing the cli command. Commits to git. The argument is the remote.

```
tebas.add
```

Equivalent of doing the cli command.

```
tebas.getDefaultGitBranch *s
```

Sets a string to the default git branch.

```
tebas.channelExists *s s
```

Sets the string to true if the channel with name 2<sup>nd</sup> arg exists, false otherwise.

```
tebas.channelList *t
```

Sets the table to the list of all channel names.

```
tebas.channelPath *s s
```

Sets the string to the path of the channel with name 2<sup>nd</sup> arg.

```
tebas.isInteractive *s
```

Sets the string to true if the terminal running tebas is interactive.

```
tebas.script s s
```

Runs a standalone script, 1<sup>st</sup> arg is the path to the script file and 2<sup>nd</sup> the arguments.

## Notes

There is a couple important things to say about sentences.

### Comments

Comments are started with '//', and they can be placed in any place of the sentence, except inside quotes or brackets.

For example:

```
//This is a valid comment  
command arg1 arg2 //This is a valid comment  
command "//This comment will be absorbed into arg1" //This is a  
valid comment
```

### File paths

When file path appear (this does not apply to the application path in the run sentence) they usually do inside of a literal.

Only local files are accessible, that means only working directory (most of the time project folder) or template directory.

You can access them with the prefixes W and T (working directory and template directory, respectively)

So you can do:

```
"W/hello.txt" //This refers to a text file in the project folder  
"T/folder1/folder2/res.dll" //Dll file in template folder
```

Only these local files can be accessed. However, there are exceptions. If a path file is not started by neither W or T in the *file.exists*, *template.create*, *plugin.create* or

*tebas.script* sentence, it will check the normal system file. Also, wildcards(\* and ?) are supported in `file.exists` and `folder.list`(and `folder.listChild`).

## String expansion

String expansion is a useful tool. It works with the format of a string. For example:

```
"Hello! Welcome to the project {%pn}"
```

If this string is expanded, the value between the curly brackets {} will be replaced. This is only valid with table references or % values.

```
f"Value: {value.0}"
```

The f literals will do this on their own on declaration, whereas normal literals will need it to be done after.

To stop this from happening and actually use the curly brackets, we can use a backslash \.

```
f"You can read \{this}"
```

## Splitting lines

Sometimes, lines get too long and it is wise to split them but keep them combined. We can do this by finishing a line with '/+'. For example:

```
console.print "This will be processed /+  
as a single line even /+  
if it is spread apart"
```
